*Lead Programmer*

areae

# Why reinvent MMOs?

---

- They are just too hard to make now
  - *Each one is a custom-crafted moon shoot.*
- Poorly integrated with rest of Internet
- Which leads to
  - *Cost: only the big kids can play*
  - *Cancellations: get it perfect or go home*
  - *Wheel reinvention: chat system #207*
  - *Lack of innovation: “make it like WoW...”*

# How MMOs work today

---

- Monolithic, giant servers
- All services contained within the server
- Complex server cluster architectures
- Tight dependency between client and server

***There are virtually no successful re-uses of MMO servers***

# How it once was

---

# ...And today

A diagram illustrating a client-server architecture. On the left, a large green circle with a black outline is labeled "Client". A thin horizontal line extends from the right side of this circle towards a dense, overlapping cluster of many smaller green circles, each with a black outline. The cluster of smaller circles fills the right two-thirds of the image, representing a server farm or a large network of servers. The background is white with a faint, repeating pattern of the word "vervet" in a light green font.

**Client**

# The alternative

---

- There exists a system which is
  - *Low cost to develop for*
  - *Extremely scalable*
  - *Robust and pretty future-proof*
  - *Highly modular and reusable*
  - *Has resulted in gigantic explosions of creativity at both pro and amateur levels*

---

# The web.

# Why does the Web work today?

**HTML**

**Mozilla**

**Apache**

**CGI**

**CSS**

**DNS**

**Google**

# An MMO that looks like the web

---

|                |                                       |
|----------------|---------------------------------------|
| <b>HTML</b>    | <i>Open markup language</i>           |
| <b>Mozilla</b> | <i>Reference browser</i>              |
| <b>Apache</b>  | <i>Assumption-free server</i>         |
| <b>CGI</b>     | <i>Scripted behaviors</i>             |
| <b>CSS</b>     | <i>Templated content</i>              |
| <b>DNS</b>     | <i>Distributed, segmented routing</i> |
| <b>Google</b>  | <i>Rich in metadata</i>               |

A diagram illustrating a client-server architecture. On the left, a large green circle with a black outline is labeled "Client". A thin horizontal line extends from the right side of this circle towards a dense, overlapping cluster of many smaller green circles, each with a black outline. These smaller circles represent servers. The word "server" is faintly visible within many of these smaller circles. The background is white with a light gray grid pattern. In the bottom right corner, there is a small, colorful logo for "Udacity" in blue and orange.

**Client**

# Server graph – MP

---

# A philosophical difference

**Put virtual worlds on  
the web,  
not the web in a virtual  
world**

- Add synchronous realtime multiuser capabilities to the web
  - *Not REST*
  - *Leverage tech from game industry that web doesn't know how to do*

# Demo

# How Metaplace was built

---

- Iterate and prototype!
- Decouple components!
- Don't optimize!
- Use what already exists!
- Start from the ridiculously simple!
  - *BASIC, flat text file, TCP socket, pipe-delimited, and see how far you can go*

# “HTML”

---

- Started handcoding tags in a text file
  - *Rigid tag structure: 10 bytes for tag*
  - *Split by pipe*
- Multiple formats for tags
  - *GML, JSON, binary, etc*
- XML schema for protocol
- Protocol negotiation

***Lesson: Verbose/inefficient protocols,  
negotiate up to efficiency***

# “Mozilla”

---

- 1<sup>st</sup> display client – BASIC!
  - *2d overhead only at first*
  - *HTTP for all assets*
- 2<sup>nd</sup> display client – Flash
- 3<sup>rd</sup> client C++
- 4<sup>th</sup> client Flash again
- 5<sup>th</sup>, just starting – standardized XML schema-based setup

**Lesson: Clients are stupid.**

# “Apache”

---

- 1<sup>st</sup> server was a text mud codebase
  - *Synchronous, basic spatial sim*
- 2<sup>nd</sup> server Twisted Python
  - *Our own stripped-down obj structure*
- 3<sup>rd</sup> server C++
  - *Platform services: spatial sim, physics, persistence, auth*
- Server gains web server
  - *Objects get URLs*
- Server gains web browser
  - *All platform services which can be moved are moved*

**Lesson: Server is as light as possible:  
a thin aggregator**

# “CGI”

---

- At first, had no behaviors at all.
- Hardcoded behaviors in Python server
- Lua backend on Python server
- Swap out Python server for C++
  - *Inline CGI is Lua*
  - *Out of process CGI is web services*
- Future: load scripts from URLs

**Lesson: Behavior is small, atomic,  
componentized, not monolithic**

# “CSS”

---

- Flat files first
  - *from text file, then from web service*
- Real time increments via tags
- Keep web service, backend to DB
  - *Client-side caching*
- XML service added
- Packaging subsets of stylesheet

**Lesson: Separate display from behavior; clients just render.**

# “DNS”

---

- Hardcoded single server
- Distributed servers, manual routing
- “Worldlist” true distributed system
- Worldlist too big, change to WNS
  - *Web exposure of server data, WNS*
  - *Web service for WNS*
- Web services for all sorts of metadata

**Lesson: Don't cram the Internet into  
your platform**

# “Google”

---

- PHP for worlds & stylesheet data
- Then two pieces: portal, stylesheet
  - *Built website on top of portal data*
  - *Built web services on stylesheet DB*
- Added Web 2.0 features to portal stuff
  - *ID, ratings, reviews, community, presence*
- Built web services to expose portal to everywhere

**Lesson: it's no good if you cannot  
find stuff/friends**

# What Went Right

---

- Use web solution when available!
- KISS! Don't design for edge cases.
- Tags! Our network stream never breaks.
- Way picky hiring
  - *Especially, the hybrid team, half web half game*
- Multiclient early: forced us to be honest
- *Don't optimize!*
  - » [Michael Jackson's](#) rules of optimization from *Principles of Program Design* (Academic Press, 1975)

**Recapitulate history with incremental platform capabilities**

# What Went Wrong

---

- Skeletal animation system.
  - *Prototype quick – actual thing never finished.*
- “Simple” in game world versus “simple” in web world – not the same!
- Needed the RPG, it’s what customers wanted.
- Content people earlier, push the pipelines.
- We fell off the multiclient bandwagon.
- Not being task-based in tool creation
